Thermochemistry Practice Problems Answer Key

Thermochemistry is a fundamental branch of chemistry that deals with the energy changes associated with chemical reactions. Practicing thermochemistry problems helps students understand concepts such as enthalpy, entropy, heat transfer, and the various laws governing energy transformations. An answer key for thermochemistry practice problems serves as an invaluable resource, allowing learners to check their work, understand mistakes, and deepen their comprehension of complex concepts. This article provides detailed solutions and explanations for a variety of thermochemistry problems, enabling students to master the subject through practical application.

Understanding the Basics of Thermochemistry

Before diving into practice problems and their solutions, it's essential to review some fundamental concepts:

Key Concepts in Thermochemistry

- **Enthalpy (H):** The heat content of a system at constant pressure.
- **Calorimetry:** The measurement of heat transfer during chemical processes.
- **Heat (q):** Energy transferred due to temperature difference.
- **Specific Heat Capacity (c):** The amount of heat required to raise the temperature of 1 gram of a substance by 1°C.
- **Enthalpy Change (ΔH):** The heat absorbed or released during a chemical reaction at constant pressure.
- **Bond Enthalpies:** The energy required to break one mole of a particular bond in a gaseous molecule.

Practice Problem 1: Calculating Heat Absorbed or Released

Problem Statement

A 50 g sample of water is heated from 25°C to 80°C. Calculate the amount of heat absorbed by the water. (Specific heat capacity of water = 4.18 J/g°C)

Solution

- Identify known values:

- Mass (m) = 50 g
- Initial temperature (Ti) = 25°C
- Final temperature (Tf) = 80°C
- Specific heat capacity (c) = 4.18 J/g°C

- Use the heat transfer formula:

\[

$$q = mc\Delta T$$

\]

where $\Delta T = T_f - T_i = 80^\circ\text{C} - 25^\circ\text{C} = 55^\circ\text{C}$

- Calculate:

\[

$$q = 50\text{ g} \times 4.18\text{ J/g}^\circ\text{C} \times 55^\circ\text{C}$$

\]

\[

$$q = 50 \times 4.18 \times 55 = 11495\text{ J}$$

\]

Answer: The water absorbs approximately 11,495 Joules of heat.

Practice Problem 2: Enthalpy Change from Combustion Data

Problem Statement

Given the combustion of methane:

The enthalpies of formation (ΔH_f°) are:

- $\text{CH}_4(\text{g})$: -74.8 kJ/mol
- $\text{CO}_2(\text{g})$: -393.5 kJ/mol
- $\text{H}_2\text{O}(\text{l})$: -285.8 kJ/mol

Calculate the standard enthalpy change (ΔH°) for the combustion of 1 mol of methane.

Solution

- Write the enthalpy change formula:

$$\Delta H^\circ = \sum \Delta H_f^\circ (\text{products}) - \sum \Delta H_f^\circ (\text{reactants})$$

- Apply the values:

$$\Delta H^\circ = [(-393.5) + 2 \times (-285.8)] - [(-74.8) + 2 \times 0]$$

(Note: Oxygen is in elemental form; $\Delta H_f^\circ = 0$)

- Calculate:

\[

$$\Delta H^\circ = (-393.5 - 571.6) - (-74.8)$$

\]

\[

$$\Delta H^\circ = -965.1 + 74.8 = -890.3, \text{ kJ}$$

\]

Answer: The combustion of 1 mol of methane releases approximately 890.3 kJ of energy.

Practice Problem 3: Bond Enthalpies and Reaction Enthalpy

Problem Statement

Using bond enthalpies:

- C-H: 413 kJ/mol
- C=O (double bond): 799 kJ/mol
- O=O: 498 kJ/mol

Calculate the approximate ΔH for the following reaction:

\[

\]

Solution

- Break bonds (endothermic step):

- Bonds broken:
- 4 C-H bonds in CH₄
- 2 O=O bonds in O₂

- Form bonds (exothermic step):

- 2 C=O bonds in CO₂
- 4 O-H bonds in 2 H₂O

- Calculate total energy to break bonds:

[

$$\text{Bonds broken} = 4 \times 413 + 2 \times 498 = 1652 + 996 = 2648, \text{ kJ}$$

]

- Calculate total energy to form bonds:

[

$$2 \times 799 + 4 \times 463 = 1598 + 1852 = 3450, \text{ kJ}$$

]

(Note: O-H bond enthalpy = 463 kJ/mol)

- Determine ΔH :

[

$$\Delta H \approx \text{Bonds broken} - \text{Bonds formed} = 2648 - 3450 = -800, \text{ kJ}$$

]

Answer: The approximate enthalpy change for the reaction is -800 kJ (exothermic).

Practice Problem 4: Enthalpy Change from a Calorimetry Experiment

Problem Statement

In an experiment, 100.0 g of water is heated from 20.0°C to 80.0°C in a calorimeter. The temperature change was measured as 60.0°C, and the calorimeter's heat capacity is negligible. Calculate the molar enthalpy change (ΔH) for the process, given the molar mass of water is 18.015 g/mol.

Solution

- Calculate the heat absorbed:

[

$$q = mc\Delta T$$

]

where:

- ($m = 100.0$, g)
- ($c = 4.18$, $\text{J/g}^\circ\text{C}$)
- ($\Delta T = 60.0$, C)

[

$$q = 100.0 \times 4.18 \times 60.0 = 25080, \text{J}$$

]

- Convert to kJ:

[

$$25.08, \text{kJ}$$

]

- Calculate moles of water:

\[

$$\text{moles} = \frac{100.0 \text{ g}}{18.015 \text{ g/mol}} \approx 5.55 \text{ mol}$$

\]

- Determine the molar enthalpy change:

\[

$$\Delta H = \frac{q}{\text{moles}} = \frac{25.08 \text{ kJ}}{5.55} \approx 4.52 \text{ kJ/mol}$$

\]

Answer: The molar enthalpy change is approximately +4.52 kJ/mol, indicating absorption of heat per mole of water.

Sample Practice Problem and Solution

Question:

A 50.0 g sample of ice at 0°C is heated until it melts and then warmed to 20°C . The heat of fusion for ice is 6.00 kJ/mol, and the specific heat capacity of liquid water is $4.18 \text{ J/g}^\circ\text{C}$. What is the total heat absorbed during this process?

- A) 334 J
- B) 502 J
- C) 1250 J
- D) 1500 J

Solution:

- Calculate moles of ice:

Molar mass of water ? 18. g/mol

Moles of ice = 50.0 g / 18. g/mol ? 2.78 mol

- Heat to melt ice (fusion):

$$Q_1 = \Delta H_f \times \text{moles} = 6.00 \text{ kJ/mol} \times 2.78 \text{ mol} = 16.7 \text{ kJ} = 16,700 \text{ J}$$

- Heat to warm water from 0°C to 20°C:

$$Q_2 = \text{mass} \times \text{specific heat} \times \text{temperature change}$$

$$Q_2 = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 20^\circ\text{C} = 50.0 \times 4.18 \times 20 = 4180 \text{ J}$$

- Total heat absorbed:

$$Q_{\text{total}} = Q_1 + Q_2 = 16,700 \text{ J} + 4180 \text{ J} = 20,880 \text{ J}$$

Answer:

None of the options exactly match, but if the options are approximate, D) 1500 J is too low, B) 502 J is too low, C) 1250 J is too low, and A) 334 J is too low. Given the calculations, the closest approximate value is about 21,000 J, indicating a potential typo in options or a need for units.

Note: The question should have options around 20,000 J for accuracy, but as per this calculation, the process demonstrates how to approach such problems.

QuestionAnswer Which of the following best describes an exothermic reaction in thermochemistry? An exothermic reaction releases heat to the surroundings, resulting in a negative ΔH value. In a calorimetry experiment, if 50 g of water absorbs 500 J of heat, what is the change in temperature? (Specific heat capacity of water = $4.18 \text{ J/g}^\circ\text{C}$) $\Delta T = 500 \text{ J} / (50 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C}) = 2.39^\circ\text{C}$ Which statement is true about standard enthalpy of formation (ΔH_f°)? It is the change in enthalpy when one mole of a compound is formed from its elements in their standard states. Given the reaction: $\text{N}_2 + 3\text{H}_2 \rightarrow 2\text{NH}_3$, which of the following indicates an exothermic process? A negative ΔH for the reaction, indicating heat is released during ammonia formation. How does increasing temperature generally affect the spontaneity of an endothermic reaction? Increasing temperature can make an endothermic reaction more spontaneous if $\Delta S_{\text{universe}}$ increases, considering $\Delta G = \Delta H - T\Delta S$. What is the primary purpose of Hess's Law in thermochemistry calculations? To determine the overall enthalpy change for a reaction by combining multiple thermochemical equations. In a reaction with $\Delta H = +100 \text{ kJ}$ and $\Delta S = +200 \text{ J/K}$, at what temperature would the reaction become spontaneous? When $\Delta G = 0$, $T = \Delta H / \Delta S = (100,000 \text{ J}) / (200 \text{ J/K}) = 500 \text{ K}$. Which of the following is NOT a standard condition for thermochemical measurements? A standard temperature of 25°C (298 K) and 1 atm pressure. If a reaction has an enthalpy change of $\Delta H = -50 \text{ kJ}$ and an entropy change of $\Delta S = 150 \text{ J/K}$, at what temperature does it become non-spontaneous? The reaction becomes non-spontaneous when $\Delta G > 0$; $T = \Delta H / \Delta S = (-50,000 \text{ J}) / (150 \text{ J/K}) = -333.33 \text{ K}$, which is physically meaningless, so it remains spontaneous at all positive temperatures. Which of the following best explains the concept of heat capacity in thermochemistry? Heat capacity is the amount of heat required to raise the temperature of a substance by 1°C or 1 K .

- Applying calorimetry data to find heat transfer.
- Estimating temperature changes during reactions.
- Relating entropy and enthalpy in thermodynamic calculations.

Sample Problems with Answers and Explanations

Below are several practice problems designed to strengthen your understanding of thermochemistry. Each problem includes a detailed solution.

Problem 1: Calculating Enthalpy Change Using Bond Energies

Question:

Given the following bond energies (kJ/mol):

- C-H: 413
- C-C: 348
- H-H: 436

Calculate the ΔH for the combustion of methane ($\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$).

Solution:

- Write the bonds broken and formed:

Bonds broken:

- In CH_4 : 4 C-H bonds
- In O_2 : 2 O=O double bonds (but since oxygen is diatomic, typically only single bonds are considered; in combustion, O-O bonds are broken)

Bonds formed:

- In CO₂: 2 C=O double bonds (each with bond energy ~799 kJ/mol)
- In H₂O: 2 O-H bonds (each ~463 kJ/mol)

- Calculate energy required to break bonds:

- Bonds broken:

$$(4 \times 413) + (2 \times 498) \text{ [since O=O double bonds are typically 498 kJ/mol]}$$

$$= 1652 + 996 = 2648 \text{ kJ}$$

- Calculate energy released by forming bonds:

- Bonds formed:

$$(2 \times 799) + (4 \times 463) = 1598 + 1852 = 3450 \text{ kJ}$$

$$\Delta H = \text{Bonds broken} - \text{Bonds formed} = 2648 - 3450 = -802 \text{ kJ}$$

Answer:

$$\Delta H = -802 \text{ kJ (exothermic reaction)}$$

Problem 2: Using Hess's Law to Find ΔH

Question:

Given the following reactions:

- $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$; $\Delta H = -393.5 \text{ kJ}$
- $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$; $\Delta H = -283 \text{ kJ}$

Calculate the enthalpy change for the reaction:

Solution:

- Write the target reaction and manipulate given reactions:

- From reaction 2: $\text{CO} + \frac{1}{2}\text{O}_2 \rightarrow \text{CO}_2$ ($\Delta H = -283 \text{ kJ}$)

- Reverse this reaction: $\text{CO}_2 \rightarrow \text{CO} + \frac{1}{2}\text{O}_2$ ($\Delta H = +283 \text{ kJ}$)

- Use reaction 1: $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$ ($\Delta H = -393.5 \text{ kJ}$)

- Add the reactions:

Adding:

Simplify:

- Calculate ΔH :

$$\Delta H = (-393.5) + (283) = -110.5 \text{ kJ}$$

Answer:

$$\Delta H = -110.5 \text{ kJ}$$

Problem 3: Heat Transfer in Calorimetry

Question:

A 50 g sample of water is heated from 25°C to 80°C. How much heat is absorbed? (Specific heat

capacity of water = 4.18 J/g°C)

Solution:

Use the formula:

$$Q = mc\Delta T$$

Where:

$$m = 50 \text{ g}$$

$$c = 4.18 \text{ J/g}^\circ\text{C}$$

$$\Delta T = 80^\circ\text{C} - 25^\circ\text{C} = 55^\circ\text{C}$$

Calculate:

$$Q = 50 \times 4.18 \times 55 = 50 \times 229.9 = 11495 \text{ J}$$

Answer:

Approximately 11,495 Joules of heat are absorbed.

Common Types of Additional Thermochemistry Problems and Their Solutions

Let's explore some typical problem types encountered in thermochemistry and how detailed answer keys approach their solutions:

1. Enthalpy of Formation Calculations

Sample Problem:

Calculate the standard enthalpy change for the combustion of methane (CH_4) given the enthalpies of formation of CO_2 and $\mathrm{H}_2\mathrm{O}$.

Answer Key Approach:

- Write the balanced combustion reaction.
- Use the formula:

$\Delta H^\circ_{\text{reaction}} = \sum \Delta H^\circ_{\text{f,products}} - \sum \Delta H^\circ_{\text{f,reactants}}$

$$\Delta H^\circ_{\text{reaction}} = \sum \Delta H^\circ_{\text{f,products}} - \sum \Delta H^\circ_{\text{f,reactants}}$$

\]

- Substitute known values, ensuring units are consistent.
- Show each calculation step clearly.
- Finalize with the calculated ΔH° .

2. Hess's Law Applications

Sample Problem:

Determine the enthalpy change for a reaction using given enthalpy changes of related reactions.

Answer Key Approach:

- Identify the target reaction and related reactions.
- Manipulate the given reactions (reverse, multiply) to match the target.
- Sum the adjusted reactions and their enthalpy changes.
- Verify the correctness of the process with a balanced reaction.
- Present the final calculated ΔH .

3. Calorimetry and Heat Capacity Problems

Sample Problem:

Calculate the heat absorbed when heating a specific mass of water from one temperature to another using calorimetric data.

Answer Key Approach:

- Use the formula:

\[

$$Q = mc\Delta T$$

\]

- Convert all units appropriately.
- If calorimeter correction is involved, include it in the calculations.
- Show the calculation of each term and the final heat absorbed.

How to Maximize the Utility of Additional Problems Thermochemistry Answers Key

Active Engagement:

Instead of passively reading solutions, learners should:

- Attempt problems independently first.
- Use answer keys to compare and analyze their approach.
- Re-solve problems after reviewing solutions to reinforce concepts.

Focus on Understanding the Methodology:

Pay attention to how the solution progresses, not just the final answer. Recognize patterns and common strategies used.

Supplement with Conceptual Review:

Use answer keys to identify areas where conceptual understanding may be lacking, then review related theory.
