At the heart of his theoretical contributions is the Schrödinger equation:

$$\hat{H} \Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_n) = E \Psi(\mathbf{r}_1, \mathbf{r}_2, \dots, \mathbf{r}_n)$$

where $\hat{H}$ is the Hamiltonian operator, Ψ the wavefunction, and E the energy. Solving this for many-electron systems involves approximations such as Kohn-Sham equations in DFT:

$$\left[-\frac{\hbar^2}{2m} \nabla^2 + V_{\text{eff}}(\mathbf{r}) \right] \phi_i(\mathbf{r}) = \epsilon_i \phi_i(\mathbf{r})$$

where V_{eff} encapsulates exchange-correlation effects. Raj's development of new exchange-correlation functionals has improved accuracy in predicting electronic properties.

Reaction Rate Equations and Energy Profiles

Reaction kinetics often involve the Arrhenius equation:

$$k = A e^{-\frac{E_a}{RT}}$$

with k as the rate constant, A the pre-exponential factor, E_a the activation energy, R the universal gas constant, and T temperature. Raj's work extends these models by incorporating

quantum tunneling effects and non-adiabatic transitions, providing a more comprehensive description of reaction rates, especially at low temperatures.

Statistical and Thermodynamic Models

Using ensemble theory, the partition function Q is central:

$$Q = \sum_i e^{-\frac{E_i}{k_B T}}$$

$$Q = \sum_i e^{-\frac{E_i}{k_B T}}$$

which allows calculation of thermodynamic properties like entropy S , enthalpy H , and free energy G . Raj has contributed to refining these calculations for complex systems, including solvated ions and nanostructured materials.
